ABSTRACT

Multiple Sclerosis (MS) is a chronic demyelinating disease of the CNS with assumed autoimmune etiology. Human herpes viruses have probable effects on relapsing-remitting MS pathogenesis presumably through molecular mimicry and/or bystander mechanisms. In this study we probed the possible contribution of the two herpes viruses; human herpesvirus 6 (HHV-6) and human herpesvirus 8 (HHV-8), in clinically definite MS (CDMS)-relapsing remitting type (RRMS) during clinical exacerbations. All patients had no history of immunomodulating or suppressing drugs intake in prior 6 months. The peripheral blood samples, from CDMS patients (n=20) (13F/7M, age (y) = 30.3±3.21) and other immune mediated neurological disorders (OIND) (11F/9M, age = 25.2±12.1), (Myasthenia Gravis, Guillain Barré Syndrome, ischemic stroke in adolescent and young adult with no clear risk factors), as a control group, had been enrolled within 15 months (January-2007 -- March-2008). We investigated the existence of specific deoxyribonucleic acid (DNA) sequences belonging to HHV-6 and HHV-8, using polymerase chain reaction (PCR) in the isolated peripheral blood mononuclear cells (PBMCs) and in plasma. PCR demonstrated HHV-6 DNA in 7 cases (35%), HHV-8 sequences in only one cases (5%) in PBMCs from 20 relapsed CDMS patients; all HHV-6 positive cases showed positive plasma results, while the blood samples from 20 OIND patients showed negative results except one case (5%) out of 9 cases of GBS was positive for HHV-8 in PBMCs. We consequently concluded that there is considerable evidence in this study that proposed the roles of HHV-6 and HHV-8 in MS pathogenesis and clinical exacerbation. (Egypt J. Neurol. Psychiat. Neurosurg., 2009, 46(1): 3-9)

INTRODUCTION

Multiple Sclerosis (MS) is a chronic demyelinating disease of the CNS with assumed autoimmune etiology that for many years have been supposed to be of potential viral triggering. Generally speaking, 85% of MS patients have relapsing remitting MS type (RRMS) in the early disease course that converted to secondary progression within 15 years in the majority of MS victims. Therefore it is considered as the most important cause of nontraumatic disability disease among young adults.¹,²

Indeed, no animal species other than humans develop MS. Even so, MS may be the consequence of a chronic viral infection, but, so far, a definitive role for HHVs in MS pathogenesis has not been established. Both HHV-6 and 8 have the same distinctiveness features (neurovirulence, neuroinvasiveness and neurotropism) of many viruses but till now there are no data that concluded in solid base the role of these viruses in development of demyelinating diseases.³,⁴,⁵

Viral neuroinvasion takes place commonly in primary acquired HHV-6 and 8 infections, although demyelination has been notified as remarkable complications. The HHVs have been isolated from MS plaques that denote a potential relation with MS pathogenesis, accordingly hindering these factors could be considered as parallel management pathway in prevention or decreasing the frequency of MS relapses, as well as, long-term disability progression.⁶

Several thoughts have been sophisticated to clarify the molecular mimicry or nonspecific bystander hypotheses of viruses. In agreement with this, two of the hallmarks of MS are sensitized auto-reactive T-cell and high auto-antibodies titers that are measurable in MS patients but not in healthy individuals. Nonetheless, many investigators using
epidemiological observations as well as the pathological characteristics consider these viruses as participants in launching and perpetuation of the disease.7,8

Whatever be, it remains possible that viral infections may trigger attacks of MS even if they do not actually cause the disease.

Aim of The Work

The rationale of this study was to investigate whether HHV-6 and 8 have a role in MS pathogenesis or not and their significant levels in relation to patients who have other immune mediated neurological disorders (Myasthenia Gravis, Guillain Barré Syndrome, ischemic stroke in adolescent and young adult with no clear risk factors).

PATIENTS AND METHODS

This study prospectively enrolled 20 individuals who have been diagnosed RRMS with exacerbation and seen by two consultant neurologists in Mansoura university hospital throughout 15 months (January-2007-- March -2008). All MS cases showed clinical, radiological and electrophysiological (visual evoked potential (VEPs) and Brainstem Auditory evoked potentials (BAEPs)) findings that confirmed RRMS diagnosis according to criteria of Poser 1983 and McDonald 2001.

The patient population was RRMS during exacerbation, the mean duration (y) of MS disease was 6.3±1.86 and EDSS score was 2.88 ± 1.06. The demographic data of our RRMS patients were 13 females and 7 males; their mean age when the included in this study was 30.3±3.21 years old. As regard the control groups, twenty cases with other immune mediated neurological disorders included in this study, their mean age when blood samples withdrawn was 25.2±12.1 years old.

Above all, we used nested PCR (nPCR) to investigate the genomic DNA of HHV-6 and PCR for HHV-8 in peripheral blood mononuclear cells (PBMC) samples of 20 relapsing-remitting MS (RRMS) patients during exacerbation as well as control group. Two blood specimens were obtained for PCR examination from every patient. Two EDTA samples were taken one for PBMC separation and the second sample for plasma. Specimens from OIND were taken by the same way.

Isolated PBMCs and plasma samples were aliquoted and stored at -70ºC. Blood samples from OIND patients were managed by the same technique. PBMCs were separated by Ficoll-Hypaque (Biotest-Germany) density gradient centrifugation and stored at -70ºC. DNA was extracted from all PBMCs samples and from plasma of positive HHV-6 cases according to the manufacturer’s instructions (Genta, Minneapolis, Minnesota). PCR was used for the detection of both HHV-6 (nPCR) and HHV-8 (PCR) sequences in PBMC-HHV-6 and 8-DNA and blood plasma for HHV-6-DNA.

nPCR-HHV-6, a 100 µL reaction (EzWay PCR master mix, Koma Biotech) contained 0.5µM of each primer and 0.5µg of DNA as a template. Negative controls were performed with sterile deionized water. The detection of HHV-6 DNA was carried out according to Bandobashi et al. 1997 with a nested primer set, complementary to the gene coding the major capsid protein, which recognizes of the virus. The nucleotide sequence of HHV-6 primers 5′-GGCTTTTCAATGTGTAGTTCGGCAG-3′ and 5′-TGCCCGCATTCGTACAGATACGGAGG-3′ (outer pairs); 5′-GCTAGAACTGTTTGGGCTCAGAAGC-3′ and 5′-ATCCGAAACAACTGACTGTCACC-3′ (inner pairs) for the first and second round of PCR, respectively.9 The inner primers amplify a 258-bp fragment of HHV-6.

The first round of PCR was carried out at 94ºC for 3 min, followed by 30 cycles of 94ºC for 1 min, 57ºC for 1 min, and 72ºC for 1 min. Terminal extension of 72ºC for 5 min was carried out after completion of the 30 cycles. A sample (10 µl) of the first round product was used as template for the second round using the conditions described for the first round.

PCR was used to amplify 233-bp fragment of HHV-8-DNA with the primers forward (GGGGAGGATTCCAAGCAT) and reverse (TTCCGTGTGTCTTCTAGTCC AG). A 100 µL reaction (EzWay PCR master mix, Koma Biotech) contained 0.5 µM of each primer and 0.5µg of DNA as a template. Negative controls were performed with sterile deionized water. Reaction mixtures were subjected to 40 cycles of the following incubations: initial denaturations at 94ºC for 2 min (1 cycle), denaturation at 94ºC for 1min, annealing at 58ºC for
1min, extension at 72°C for 2min (40 cycles) and final extension at 72°C for 5min.

A thermal cycler (Peltier-effect cycling, MJ Research, Inc.) (Watertown Mass) was used for the both PCR reactions. For detection of amplified DNA of both HHVs, ten µL from the amplicon were analyzed by electrophoresis (Haefer HE33) in 2% agarose gel with 1x TBE buffer stained with ethidium bromide, visualized under UVL (Fisher Biotech, FBTV-88) and photographed against DNA molecular size marker (Ø X174 Hae III) (FB-PDH-1216).

All positive PBMC-HHV-6-DNA-PCR cases were analyzed again for plasma HHV-6-DNA for more confirmation. In this study we will discuss the results of PBMC samples because it is done for all patients but PCR for plasma samples were done for HHV-6-MS positive cases only.

Statistical analysis of data are given as mean±SD. Continuous data were analyzed by the independent t test, as appropriate. P value of less than 0.05 was regarded as statistically significant.

**RESULTS**

Between January 2007, and March 2008, 40 patients’ blood samples were collected in Neurology department, Mansoura University, There were 20 patients who had been classified as CDMS according to published Poser and McDonald criteria of MS diagnosis, all of them are RRMS type and investigated during relapse. The control group included twenty patients who had other immune related neurological diseases.

Indeed, this prospective study significantly estimated the proportion of HHV-DNA sequences positive cases in comparison with prospectively classified OIND. The OIND spectrum comprised 9 cases with Guillain Barré Syndrome, 5 for Myasthenia Gravis, and 6 patients had ischemic stroke in adolescent and young adult with no clear risk factor (Table 1).

The clinical characteristics of each group in our study were compatible with so-called immune based neurological disorder, either B-cell or T-cell mediated, just to exclude the possibility of cross immunity, dominating one type of immune reaction or B-T cell conversion immunoprocess.

Among RRMS cases there were seven patients (35%) showed positive results for HHVs-DNA sequences. Pin pointing to the type of HHVs, The study implicated the relatively high frequency of HHV-6 DNA sequence in 7 cases (35%), HHV-8 sequence in only one case (5%) in PBMCs that was drawn from 20 RRMS patients throughout exacerbation; all patients had no history of immunomodulatory or immunosuppressive treatments intake 6 months prior to the last attack (Table 2 and Fig. 1).

There was one female patient who showed positive DNA sequence for both HHV-6 and 8 and her EDSS score was 5.5. This patient also experienced high frequency of MS exacerbation.

The PCR of the blood samples that had been drawn from twenty OIND patients showed no positive DNA sequence for HHV-6 or 8 except one case out of 9 cases of GBS (11.1%) was positive for HHV-8 that represent 5% of the total OIND patients (Tables 1 and 2). There was no significant predilection to females. Three out of the seven patients (42.8%) who had positive HHV-6-DNA sequences as well had high EDSS scores (more than 4).

HHV, human herpesvirus; n, number.

**DISCUSSION**

The goal of this work was to clarify the incidence of human herpes viruses (HHV-6 and HHV-8) among MS patients during relapses that have often present significantly (35%) in blood samples of RRMS patients more than control group (%5) (p<0.05). This is indicating that viral agents could contribute to demyelination plaques and MS pathogenesis.5,6, 9,11,12

Moreover there is significant increase in frequency of relapses and severity of MS disease among HHVs positive patients (42.8%) (p<0.05) who showed relative high EDSS. The percentage of cases with positive HHV-6 is higher thanHHV-8,5,13

In harmony with our results, Simmons 2001 and others stated that HHV-6 DNA correlates with active HHV-6 infection and is not found in healthy individuals. In this distinctive study, IgM titers showed a considerable raise to the p41/38 early antigen in patients with RRMS, in comparison to
healthy controls and individuals with other neurological disease.\textsuperscript{14,15,16}

Two further studies have established the existence of increased IgM responses to HHV-6 in patients with MS. Additionally, HHV-6 DNA was identified in 30\% of MS patients (15 of 50) and in 0\% of 47 controls consisting of healthy individuals, patients with other inflammatory diseases, and patients with other neurological diseases, despite the fact that no correlation was demonstrated in Enbom, 2001 study.\textsuperscript{5,18,19}

Knox et al. (1998), stated that HHV-6 may host CNS of MS patients and activated, as measured by DNA in plasma and CSF, from time to time. Anyhow, HHV-6 A variant was detected in the PBMC of MS patients but not in controls.\textsuperscript{20}

It has been proposed that disagreements in these results may be caused by variations in reagents, procedures, racial and patient selection. Further serological, cellular/immune response, molecular, and clinical studies are required to explain the task of HHV-6 and 8 in MS pathogenesis.\textsuperscript{21}

Clearly, there is one patient who had HHV-8 (5\%) with high EDSS that did not show significant differences with control group, which denotes the modest role of HHV-8 in disease progression and relapses frequency more than MS pathogenesis.\textsuperscript{22}

However, it is of interest that, when other investigators studied HHV-6 and 8 in RRMS, they gave attention to virus immunoglobulin titers and DNA but they did not correlate both of them with exacerbation.\textsuperscript{23,24} Therefore, our distinctive study focus on the role of HHVs during relapses, this higher percentage of positive cases in relation to other studies may denote a considerable relation between exacerbation and HHVs, in addition to HHVs potential task in MS pathogenesis, plus all cases in this study had not receive any of beta-interferon drugs that have potential antiviral effects. As well racial factor may play also an important role in this high percentage.

**Conclusion**

We concluded that there is sizeable evidence in this study that put forward the association of HHV-6 and HHV-8 with RRMS during exacerbation. At the same time we have to be watchful to explain this mysterious disease very simply on the base of chronic viral infection, but we support extremely Egyptian therapeutic trials which put forward the role of antiviral drugs (acyclovir or valacyclovir) in treatment of MS exacerbation via evaluation of viral serology, radiological as well as immunological outcomes and the effect of these drugs on long term disease disability.\textsuperscript{25,26}

يعتقد أن مرض التصلبات المتزامنة بالجهاز العصبي المركزي من الأمراض الناتجة عن خلل بالجهاز المناعي للإنسان.

ومع الأمراض الرئيسية التي تؤدي إلى عجز في سن الرشد, وتشير الأبحاث المتعددة إلى أن الفيروسات من الأسباب المؤدية أو المبررة لنووات مرض التصلبات المتزامنة.

هكذا، في هذه الدراسة معرفة المساهمة المحتملة لتنوع الفيروسات الحلالية البشرية (السادس والثامن) لحالات مرض التصلبات المتزامنة المثبتة إكلينيكياً (النوع المنكس المرتدي) وذلك خلال فترة التفاهم الإكلينيكي لهذا المرض.

تم اختيار المرضى (20 مريضاً) (13 ذكور وتذكرة) بمعدل عمري (30.3±3.21 عاماً) في الفترة من يناير 2007 وحتى مارس 2008 مع مراعاة خلو هؤلاء المرضى من أي تاريخ مرضي لتعاطي أدوية مضادة أو منظمة للمناعة ستهور على الأقل قبل بدء الدراسة. كذلك تم اختيار مجموعة ضابطة عددها 20 شخصاً (11 ذكر و 9 مريضة) بمعدل عمري (25.2±12.1 سنة) وهذه المجموعة الضابطة مرضى بأمراض عصبية مناعية مثل (مرضى وذوي العائلات - مرضى متلازمة جيلان بارى - مرضى السمنة الشاملة ناتجة بالثقة الوراثية في صحار السمن في غياب عوامل خطيرة مثيرة). تم سحب عينات الدم من المجموعتين للبحث عن تواجد سلالات الفيروس النووي (DNA) الخاصة بالفيروسين الحلاليين البشرين.

(السادس والثامن) مستخدمين اختبار (PCR) داخل خلايا الدم 혐وية النواة وكذلك في البلازما.

أثبت اختبار (PCR) وجود الفيروس الحلالي السادس في عدّ 7 حالات بنسبة (35%) والفيروس الحلالي الثامن في حالة واحدة فقط بنسبة مئوية (5%) من إجمالي عدّ عشر مريضاً بمرض التصلبات المتزامنة (النوع المنكس المرتدي) مع ملاحظة أن كل الحالات الإيجابية لفيروس الحلالي السادس كانت أيضاً إيجابية في البلازما في حين لم تثبت اختبار (PCR) وجود الفيروس الحلالي في المجموعة الضابطة إلا في مريض واحد بمرض متلازمة جيلان بارى بنسبة مئوية (5%) وكان الفيروس الحلالي الثامن. وبإضافةً إلى هذه الدراسة تستطيع أن نخلص إلى أن هناك دور جدير بالإعتبار للفيروس الحلالي البشري (السادس والثامن) في نشوء مرض التصلبات المتزامنة وخصوصاً في فترة التفاهم الإكلينيكي لهذا المرض.
